For more than a decade the formation of new aerosol particles in the atmosphere has been the subject of intense studies in both, field and laboratory. $\mathrm{H}_{2} \mathrm{SO}_{4}$ was ascertained to play a central role in this process. A dominante pathway of $\mathrm{H}_{2} \mathrm{SO}_{4}$ generation represents the OH radical initiated oxidation of $\mathrm{SO}_{2}$. Recently it was discovered that also other oxidants than OH radicals, very likely stabilized Criegee Intermediates (sCI), can significantly contribute to $\mathrm{H}_{2} \mathrm{SO}_{4}$ formation under atmospheric conditions (Mauldin et. al., 2012). Criegee Intermediates originate from the reaction of ozone with unsaturated substances (olefins) and occur with different structures associated with a different chemical behaviour. Unfortunately, the formation yields of sCI as well as their chemical reactivity toward atmospheric trace gases ( $\mathrm{SO}_{2}$, acids, etc.) and water vapour are not well characterized and are, at least partly, subject of speculation. Welz et. al. (2012) reported on unexpectedly high rate coefficients of the reaction of $\mathrm{CH}_{2} \mathrm{OO}$ with $\mathrm{SO}_{2}$ and other trace gases. As a result from our laboratory, clearly lower rate coefficients for the reaction of a series of sCI with $\mathrm{SO}_{2}$ have been measured (Berndt et. al., 2012). Generally, there is a debate at the moment regarding the relevance of the $\mathrm{sCI}+\mathrm{SO}_{2}$ reaction in competition with the probably, much more important $\mathrm{sCI}+\mathrm{H}_{2} \mathrm{O}$ pathway.

This experimental study focuses on $\mathrm{H}_{2} \mathrm{SO}_{4}$ formation from the ozonolysis of tetramethylethylene (TME) and trans-2-butene in the presence and absence of an OH radical scavenger at atmospheric pressure conducted in the temperature range of $278-343 \mathrm{~K}$ and a relative humidity of 8 $60 \%$. The experiments have been performed in a flow tube (IfT-LFT) for close to atmospheric reactant concentrations, [olefin] $=(1-4) \cdot 10^{10}$ molecule $\mathrm{cm}^{-3}$, $\left[\mathrm{O}_{3}\right]=2 \cdot 10^{11}$ molecule $\mathrm{cm}^{-3} . \mathrm{H}_{2} \mathrm{SO}_{4}$ was detected by means of a high resolution mass spectrometer with a chemical ionization inlet, CI-APi-TOF, utilizing $\mathrm{NO}_{3}{ }^{-}$ ions for chemical ionization (Jokinen et. al., 2012). In the case of the ozonolysis of TME, additional $\mathrm{H}_{2} \mathrm{SO}_{4}$
formation in the presence of the OH radical scavenger showed no clear RH dependence. In the trans-2-butene system, however, distinct RH-dependent $\mathrm{H}_{2} \mathrm{SO}_{4}$ production was detected, see for instance figure 1. The observed effects point to the occurrence of two oxidants for $\mathrm{SO}_{2}$ (beside OH radicals) with different chemical behaviour, probably the syn- and anticonformers of acetaldehyde oxide.

Figure 1: Ratio of measured $\mathrm{H}_{2} \mathrm{SO}_{4}$ at $\mathrm{RH}=10$ and $50 \%$ as a function of $\mathrm{SO}_{2}$ concentration, presence of an OH radical scavenger, 293 K.
